Introduction

The “PAWN” programming language depends on a host application to provide an interface to the operating system and/or to the functionality of the application. This interface takes the form of “native functions”, a means by which a PAWN script calls into the application. The PAWN “core” toolkit mandates or defines *no* native functions at all (the tutorial section in the manual uses only a *minimal* set of native functions in its examples). In essence, PAWN is a bare language to which an application-specific library must be added.

That notwithstanding, the availability of general purpose native-function libraries is desirable. The “Time Functions Library” discussed in this document intends to be such a general-purpose module.

This application note assumes that the reader understands the PAWN language. For more information on PAWN, please read the manual “The PAWN booklet — The Language” which is available from the company homepage.

Implementing the library

The “Time Functions Library” consists of the two files `AMXTIME.C` and `TIME.INC`. The C file may be “linked in” to a project that also includes the PAWN abstract machine (`AMX.C`), or it may be compiled into a DLL (Microsoft Windows) or a shared library (Linux). The `.INC` file contains the definitions for the PAWN compiler of the native functions in `AMXTIME.C`. In your PAWN programs, you may either include this file explicitly, using the `#include` preprocessor directive, or add it to the “prefix file” for automatic inclusion into any PAWN program that is compiled.

The “Implementer’s Guide” for the PAWN toolkit gives details for implementing the extension module described in this application note into a host application. The initialization function, for registering the native functions to an abstract machine, is `amx_TimeInit` and the “clean-up” function is `amx_TimeCleanup`. In the current implementation, calling the clean-up function is not required.

If the host application supports dynamically loadable extension modules, you may alternatively compile the C source file as a DLL or shared library. No explicit initialization or clean-up is then required. Again, see the Implementer’s Guide for details.

Usage

Depending on the configuration of the PAWN compiler, you may need to explicitly include the `TIME.INC` definition file. To do so, insert the following line at the top of each script:

```
#include <time>
```

The angle brackets “<...>” make sure that you include the definition file from the system directory, in the case that a file called `TIME.INC` or `TIME.P` also exists in the current directory.

From that point on, the native functions from the file I/O support library are available.

The `settimer` function sets up the interval (or the *delay* for a one-shot timer) for the `@timer` callback function. To get a time event, the script must implement the `@timer` callback function and configure the timer with `settimer`.

An event-driven program that prints a period (“.”) every second is:

LISTING: event-driven program to print a dot each second

```
#include <time>

main()
    settimer 1000          /* interval is in milliseconds */

    @timer()
        print "."
```

For comparison, below is a flow-driven program that does the same thing. It needs two loops: an inner loop to check for overflowing a second and an outer loop to continue printing dots after each second lapse. The program below is designed for purpose of demonstration, instead of timing quality. As it is, it is prone to timer drift. The event-driven alternative above is more accurate.

LISTING: flow-driven program to print a dot each second

```
#include <time>

main()
{
    for ( ;; )
    {
        new stamp = tickcount()
        while (tickcount() - stamp < 1000)
        {}
        print "."
    }
}
```

Public functions

@timer	A timer event occurred
Syntax:	<code>@timer()</code>
Returns:	The return value of this function is currently ignored.
Notes:	<p>This function executes after the configured delay or interval expires. See <code>settimer</code> to set the delay or interval. Depending on the timing precision of the host, the call may occur later than the delay that was set.</p> <p>If the timer was set as a “single-shot”, it must be explicitly set again for a next execution for the <code>@timer</code> function. If the timer is set to be repetitive, <code>@timer</code> will continue to be called with the set interval until it is disabled with another call to <code>settimer</code>.</p>
See also:	<code>delay</code> , <code>settimer</code>

Native functions

<code>cvttimestamp</code>	Convert a time-stamp into a date and time
---------------------------	---

Syntax: `cvttimestamp(seconds1970, &year=0, &month=0,
&day=0, &hour=0, &minute=0,
&second=0)`

year This will hold the year upon return.

month	This will hold the month (1-12) upon return.
-------	--

day This will hold the day of (1-31) the month
 upon return.

hour This will hold the hour (0-23) upon return.

minute	This will hold the minute (0-59) upon return.
--------	---

second This will hold the second (0-59) upon return.

Returns: This function always returns 0.

Notes: Some file and system functions return time-stamps as the number of seconds since midnight, 1 January 1970, which is the start of the UNIX system epoch. This function allows to convert these time stamps into date and time fields.

See also: [gettime](#), [getdate](#), [settimestamp](#)

delay	Halts execution a number of milliseconds
-------	--

Syntax: `delay(milliseconds)`

milliseconds

The delay, in milliseconds.

Returns: This function currently always returns zero.

Notes: On some platforms, the `sleep` instruction also delays for a given number of milliseconds. The difference between the `sleep` instruction and the `delay` function is that the `delay` function does not yield events and the `sleep` instruction typically yields. When yielding events is, any pending events are handled. As a result, the `delay` function waits *without* handling any pending events and the `sleep` instruction waits and deals with events.

See also: [tickcount](#)

getdate Return the current (local) date

Syntax: `getdate(&year=0, &month=0, &day=0)`

year	This will hold the year upon return.
month	This will hold the month (1-12) upon return.
day	This will hold the day of (1-31) the month upon return.

Returns: The return value is the number of days since the start of the year. January 1 is day 1 of the year.

See also: [gettime](#), [setdate](#)

gettime Return the current (local) time

Syntax: `gettime(&hour=0, &minute=0, &second=0)`

hour	This will hold the hour (0-23) upon return.
minute	This will hold the minute (0-59) upon return.
second	This will hold the second (0-59) upon return.

Returns: The return value is the number of seconds since midnight, 1 January 1970: the start of the UNIX system epoch.

See also: [getdate](#), [settime](#)

setdate Set the system date

Syntax: `setdate(year=cellmin, month=cellmin,
 day=cellmin)`

year The year to set; if set to “cellmin”, the default value, it is ignored.

month The month to set; if set to “cellmin”, the default value, it is ignored.

day The month to set; if set to “cellmin”, the default value, it is ignored.

Returns: This function always returns 0.

 The date fields are kept in a valid range. For example, when setting the month to 13, it wraps back to 1.

See also: [getdate](#), [settime](#), [settimestamp](#)

settime Set the system time

Syntax: `settime(hour=cellmin, minute=cellmin,
 second=cellmin)`

hour The hour to set, in the range 0-23; if set to “cellmin”, the default value, it is ignored.

minute The minute to set, in the range 0-59; if set to “cellmin”, the default value, it is ignored.

second The second to set, in the range 0-59; if set to “cellmin”, the default value, it is ignored.

Returns: This function always returns 0.

 The time fields are kept in a valid range. For example, when setting the hour to 24, it wraps back to 23.

See also: [gettime](#), [setdate](#), [settimestamp](#)

settimer Configure the event timer

Syntax: `settimer(milliseconds, bool: singleshot=false)`

`milliseconds`

The number of milliseconds to wait before calling the `@timer` callback function. Of the timer is repetitive, this is the interval. When this parameter is 0 (zero), the timer is shut off.

`singleshot` If false, the timer is a repetitive timer; if true the timer is shut off after invoking the `@timer` event once.

Returns: This function always returns 0.

Notes: See the chapter “Usage” for an example of this function, and the `@timer` event function.

See also: `@timer`, `tickcount`

settimestamp Sets the date and time with a single value

Syntax: `settimestamp(seconds1970)`

`seconds1970`

The number of seconds that have elapsed since 00:00 hours, 1 January 1970. This particular date, 1 January 1970, is the “UNIX system epoch”.

Returns: This function always returns 0.

Notes: The function `getdate` returns the number of seconds since 1 January 1970.

See also: `getdate`, `setdate`, `settime`

tickcount Return the current tick count

Syntax: `tickcount(&granularity=0)`

granularity

On return, this parameter has the timer precision, as the number of ticks per second.

Returns: The number of milliseconds since start-up of the system. For a 32-bit cell, this count overflows after approximately 24 days of continuous operation.

Notes: If the granularity of the system timer is “100”, the return value will still be in milliseconds, but the value will change only every 10 milliseconds (100 “ticks” per second is 10 milliseconds per tick).

This function will return the time stamp regardless of whether a timer was set up with **settimer**.

See also: **settimer**

Resources

The PAWN toolkit can be obtained from www.compuphase.com in various formats (binaries and source code archives). The manuals for usage of the language and implementation guides are also available on the site in Adobe Acrobat format (PDF files).
